

# Ubbelohde Memorial Lecture

As mentioned earlier, Professor Ubbelohde of Imperian College, London, was a central figure in the early UK carbon conferences. The British Carbon Group is pleased to inaugurate what is hoped to be an annual Ubbelohde Memorial Lecture at this conference, and we are especially delighted that Professor Sir Harry Kroto has found the time to deliver the first lecture on Monday July 17<sup>th</sup>, 2006 in the MacRobert Hall.

Professor Kroto has provided the following introduction to his lecture:

**Architecture in NanoSpace**  
**Harold Kroto**  
**The Department of Chemistry and Biochemistry**  
*The Florida State University*  
**Tallahassee Florida 32306-4390 USA**

As Chemistry and Physics at one borderline and Chemistry and Biology at the other begin to become indistinguishable, multidisciplinary research is leading to the fascinating “new” field of Nanoscience and Nanotechnology (N&N – not to be confused with M&M). Ingenious strategies for the creation of molecules with complex exactly-specified structures and as well as function are being developed – basically molecules that do things are now being made. In fact N&N may be considered “*Frontier Chemistry of the 21<sup>st</sup> Century*”.

When the molecule C<sub>60</sub>, Buckminsterfullerene, and its elongated cousins, the carbon nanotubes (or “Buckytubes”), were discovered it suddenly became clear that our previous understanding of the structural and dynamic factors governing carbon chemistry at nanometer scale were wrong. New experimental vapour and condensed phase approaches, often involving metal cluster catalysis, have led to the production of novel refractory nanostructures. Studies of composites involving these new materials are beginning to exhibit interesting advanced materials behaviour. Fascinating fundamental insights into their formation mechanisms have also been revealed and the creation of nanoscale devices, which parallel devices used in standard engineering are now being made.

On the horizon are numerous exciting possible applications in numerous diverse areas ranging from civil engineering to advanced molecular electronics so promising to transform our lives and global economics. We now know we should one day be able to build buildings so strong that they will not fall down in Earthquakes and aeroplanes so light that they will be able to glide to safety if the engines fail. We should be able to construct supercomputers that will fit in your wrist watch and surgical techniques which will enable us to carry out medical operations almost non-invasively. If these prospects are to be realised however a paradigm shift in synthetic control strategies will be necessary to create really large molecules with accurately defined structures at the atomic level. This presents one of the greatest technical challenges for 21<sup>st</sup> Century Chemists. From a fundamental research strategy viewpoint it is worth noting the fact that the original C<sub>60</sub> discovery experiments were carried out as a consequence of earlier molecular spectroscopy/radioastronomy discoveries relating to material in interstellar space and red giant carbon stars, together with the development major advances in our techniques for studying small refractory clusters.
